

## Highlights

- A novel approach, the **Temporal Dominance of Behavior (TDB)**, has been proposed to summarize, visualise and interpret video observation data.
- The **TDB** approach provides a dynamic graphical synthesis of the subjects' eating behavior.
- Consumption dynamic is related to both dish and consumer characteristics.
- The analysis of bread consumption behavior highlights strong individual variations.
- Different consumer groups have been drafted.

Traditional approaches to data analysis of video observations are based on static counts reporting the number of times an action occurs, disregarding the dynamic aspects captured in the video. In this paper, we investigate French consumers' bread consumption patterns during a restaurant meal. We propose a novel approach, the **Temporal Dominance of Behavior (TDB)**, to visualise the dynamic information contained in video material in terms of frequency, duration, sequence and simultaneity of actions based on standard data analysis principles from temporal methods such as Temporal Dominance of Sensations (TDS) and Temporal Check-All-That-Apply (T-CATA). **TDB** allows reporting hours of videos across several subjects in a single graphical output, providing an efficient summary overview suitable for results interpretation and communication.

Regarding bread consumption patterns during a restaurant meal in French consumers, three groups of consumers are drawn: the No-breaders (43%), the Bread-as-a-tool group (48%) and the Bread lovers (9%). Eating behavior varies in the consumed quantity of bread as well as in consumption dynamics throughout the meal, and it is related to both the type of dish that is consumed and to consumer characteristics. The Temporal Observation Curves approach provides a graphical synthesis of the dynamic information.

We discuss the added-value of the **TDB** method compared to single-point analysis, provide recommendations for future developments and suggest potential applications in the consumer and food domain.

## 1. Introduction

In the late 20th century, Meiselman (1992) already suggested the need for a sensory evaluation that resembled how people ate in the real world, because consumption behavior is different outside of the laboratory. In the recent years, different approaches have been proposed to study consumer behavior without disturbance, such as postmeal self-reports (Haugaard, Brockhoff, & Lähteenmäki, 2016), in which researchers photographed subjects' meals after they freely chose dishes at a commercial buffet, and then asked them some questions. Even if self-report data have been extensively useful (Lahne, 2018), they can be biased as subjects may not recall their behavior accurately, some actions being done unconsciously. Alternative approaches, such as observational methods, could then be considered. Consumer scientists and professionals look for intermediate ways between real-life and laboratory conditions to improve the ecological validity of experimental environments. The principle of a living lab is to collect consumer data in a real environment but keeping the control of contextual factors. To keep the realism of the consumption experience, technological equipment is used to record relevant data from users who have agreed to be observed (Giboreau, 2018). Meals could be audio and/or video recorded, then transcribed and coded in reference to the meal itself to gain insight on the experience of the participants.

Working in teaching restaurants at a culinary school provides a wonderful opportunity to control the meal without completely disrupting the meal context (Porcherot et al., 2015). The living lab technological system allows researchers to record video and evaluate the dynamics of food consumption together with the measurement of the liking of food at different moments in the meals. This is a complete approach which provides information on food appreciation concerning the kinetics of consumption (Allirot et al., 2014; Clicerri, 2018; Fernandez, Bensafi, Rouby, & Giboreau, 2013). Liking and actual consumption are not always correlated and emphasize the value of conducting multiple-level approaches and real-life situation studies (Iborra-Bernad, Saulais, Petit, & Giboreau, 2018).

67 Living lab experiments can be seen as an attempt to compromise with the limitations and advantages  
1  
268 of laboratory and field experiments, as the control of contextual variables increases the internal  
3  
469 validity of the study, while the situation is kept as ecological as possible (Galinanes Plaza, Delarue,  
6  
70 & Saulais, 2019). “The Restaurant of the Future” in Wageningen, Netherlands (Hinton et al., 2013;  
8  
971 Zeinstra, Koelen, Kok, & de Graaf, 2010), “The Grill Room” in Bournemouth, United Kingdom  
10  
11  
1272 (Bell, Meiselman, Pierson, & Reeve, 1994; Meiselman, Johnson, Reeve, & Crouch,2000) and “The  
13  
1473 Living Lab” at the Research Centre of the Institute Paul Bocuse in Ecully, France (Porcherot et al.,  
15  
16  
1774 2015, Dougkas, Vannereux, & Giboreau,. 2019) are examples of Living labs dedicated to food  
18  
1975 studies.  
20  
21  
2276 In the last 50 years, there has been limited interest in recording eating behavior by video, as  
23  
2477 demonstrated by ScienceDirect, which reports 303 publications since 1971 (search with keywords:  
25  
2678 eating/drinking behavior, video, camera). Among them, 162 also include the keyword meal, of which  
27  
28  
2979 61 concern the adult population (i.e. excluding particular consumer categories, such as child, children  
30  
31  
3280 and elderly). Among those studies, 29 used video to induce emotions or contexts and only 32  
33  
3481 recorded meal situations and analyzed the videos, focusing the attention on the effect of the context  
35  
3682 on consumption, perception, emotions (9), on validation of methodologies (7), on food choices (4)  
37  
38  
3983 and other various topics. Only 4 out of 32 publications focused on consumption dynamics. Kissileff  
40  
4184 (Kissileff, Thornton, & Becker, 1982) modelled the dynamics of food intake in humans as a  
42  
43  
4485 quadratic equation, defining three types of eaters: those who show a linear relationship between food  
45  
4686 intake and time, those who show an accelerated relationship (eating slowly in the beginning and fast  
47  
48  
4987 at the end) and those who show a decelerated one. Two studies (Westerterp, Nicolson, Boots, &  
50  
5188 Mordant, 1988; Westerterp-Plantenga et al., 1990) analyzed the consumption dynamics in obese and  
52  
53  
5489 normal subjects, assessing the influence of inter-individual variability. In both studies, the authors  
55  
5690 constructed cumulative contribution curves as a function of time and used quadratic equations to fit  
57  
58  
5991 data and conformed Kissileff’s model. Some years later, other scientists (Ioakimidis et al., 2012)  
60  
6192 described dietary intake in relation to the evolution of chewing sequences during meals, and

93 consumers were split into two groups: linear and decelerated eaters. They found that decelerated  
1  
24 eaters took fewer and smaller bites for the last third of the meal. The chewing frequency was the  
3  
4  
5 same for all and constant during the meal. Alliot et al. (2012) showed good intra-individual  
6  
7  
8 repeatability of eating dynamics over three days. Finally, several studies showed the influence of  
9  
10  
11 contextual factors on the dynamics of eating or drinking patterns and consumer satisfaction (e.g.

Noldus' Observer XT 12.0 Behavioral Analysis Software (Wageningen, the Netherlands) can be  
used to record and analyze the actions of the studied subjects, such as food intakes or social  
interactions during a meal. It is a standard tool to record the times, occurrences and durations of  
various behaviors of the subjects under study (Sun, 2018). However, those results are generally  
reported in terms of frequency of actions in table or bar chart format (e.g. El Khoury et al., 2015,  
Masson, Delarue, & Blumenthal, 2017), or in terms of nutritional characteristics of food intake over  
time (Alliot et al., 2014). To our knowledge, until now no approaches have been proposed to  
visualise video-recorded data by drafting a dynamic graph of consumer behavior over time in a meal  
situation and taking into account the diversity of consumer actions and food items. **Video  
observation is a very interesting tool for studying consumer behavior, but it is necessary to find a  
graphic presentation that is easy and quick to interpret. In the last years, in the field of sensory  
analysis, several methods for evaluating sensory profiles over time have been developed such as  
Temporal Dominance of Sensations (TDS) (Pineau et al, 2009), Temporal Check-All-That-Apply  
(TCATA) (Castura, Antúnez, Giménez, & Ares, 2016), multi-attribute time-intensity (MATI)  
(Kuesten, Bi, & Feng, 2013) and Progressive profile (PP) (Esmerino et al, 2017). Among them the  
TDS method allows determining which sensory attribute predominates over time (Pineau & Schilch,  
2015), with results presented as average dominance curves, showing the proportion of attributes**

119 dominance against time. The method has also been extended to temporal measures of wanting,  
1  
120 satiation and emotion (Schlich 2017). Inspired by TDS principles, the present publication explores a  
2  
3  
4  
121 translation of temporal methods from sensory profiling to the domain of consumer behavior in video  
5  
6  
122 observations.

7  
8  
9  
123 The French people have a dear relationship with bread. It is a highly traditional product, part of the  
10  
11  
124 national food identity and heritage, and it is no wonder that the French baguette is a symbol of  
13  
14  
125 Frenchmen (Ginon et al., 2009; Crucean et al., 2019). The average bread consumption in France is of  
15  
16  
126 about 120 g day per capita corresponding to 26% of carbohydrate, 22% of fiber and 25% of salt  
17  
18  
127 intake in French adults (Planetoscope, 2019; CREDOC 2016; Crucean et al., 2019). Bread is a steady  
19  
20  
21  
228 component of breakfast, lunch and dinner in most French households, mostly in the form of the  
23  
24  
249 traditional French baguette, but also in various alternative shapes and recipes (whole grain, organic,  
25  
26  
2730 gluten-free etc.). In France bread seldom constitutes the principal element of a meal (e.g. open  
27  
28  
29  
30 sandwiches in the Scandinavian culture), but is rather available as an accompaniment to the foods  
31  
32  
3132 consumed with cutlery in a plate. In this context, bread typically serves as a tool to for example push  
33  
34  
343 food on one's fork, wipe one's plate and cutlery clean before the next dish is served, or consume the  
35  
36  
3634 sauce of a dish. A previous work on bread consumption by French consumers used video-recording  
37  
38  
3935 to collect information on each piece of bread eaten during a meal. This was done thanks to the  
40  
41  
4136 simultaneous use of VIC media player and Excel 2007 (respectively to watch and code behaviors)  
42  
43  
437 and allowed the creation of a grid analysis (Iborra-Bernad et al., 2018). However, no overall  
44  
45  
4638 temporal behavior was reported through this approach.

47  
48  
139 As bread is generally consumed during the whole meal, it is interesting to assess bread-related  
49  
50  
5140 behavior of consumers at the restaurant. To our knowledge, no previous research has investigated  
52  
53  
5341 bread consumption patterns within the frame of a meal; there is therefore a need for exploratory  
54  
55  
542 research in this domain. Bread consumption during a meal could affect the hedonic appreciation of  
56  
57  
5843 the whole meal or a particular plate, e.g. it could be consumed with a portion of food in a bite (van  
59  
60  
6144 Eck & Stieger, 2020), but it surely has an impact on nutritional intake and satiety (Touyarou et al.,

145 2012). Consumer clusters are increasingly studied also based on differences in food attitudes to  
1  
146 obtain useful information to characterize the different consumer segments. Understanding  
3  
147 consumers' bread usage during a meal may provide useful insights to food product developers and to  
4  
6  
148 the hospitality sector for composing menus in canteens as well as in restaurants, e.g. improving the  
8  
149 nutritional value of the meal and/or selecting the appropriate bread portion and composition.  
10  
150 Starting from those considerations, the main objective of the present paper was to propose a  
11  
151 graphical way to present data from an observatory study, allowing to show the relationship between  
13  
152 food intake and time as well as the diversity of behaviors due to various eaten foods. The proposed  
14  
153 method draws inspiration from TDS curves to visualize which actions or events are dominant at any  
15  
21  
224 given moment over time in a set of consumers sharing a common situation. In particular, the  
23  
245 proposed Temporal Dominance of Behavior (TDB) approach is used to assess the effect of dish  
25  
256 characteristics on consumers' bread consumption behavior, and to study consumer profiles according  
26  
257 to individual consumers' relationship with bread throughout the meal. The paper's ambition is to  
27  
31  
158 present a new concept that may be useful and inspiring to other researchers interested in video  
32  
33  
345 observation. We also discuss several avenues for future developments, hoping that the paper may  
35  
360 inspire qualified statisticians to further develop the analytical approach and answer the challenges  
37  
38  
361 associated with observational data.

## 41 2. Materials and methods

### 43 2.1 Ethics

45  
464 The study was conducted according to the guidelines laid down in the Declaration of Helsinki and  
47  
48  
165 General Data Protection Regulation (GDPR), and they were approved by the Research Protocol  
49  
50  
5166 Committee of Institut Paul Bocuse according to national ethics guidelines (Loi Jardé, n 2012-300, 12  
52  
53  
167 March 2012). Written informed consent was obtained from all consumers before their participation  
54  
55  
568 in the study, including a video recording consent form.

### 60 2.2. Contextualized test

171 The test was performed at the Living Lab of the Institut Paul Bocuse Research Center. It is an  
1  
172 experimental restaurant made up of a dining room and a kitchen entirely adjustable and equipped  
3  
173 with a video recording system. This restaurant is open some periods of the year and while they book,  
4  
6 clients are informed that they may take part in a research study involving to answer a questionnaire  
774 and/or being filmed during their meal.  
8  
9  
175

## 11 1276 13 14 2.3 Participants 15

16 A total of 133 French consumers participated in the study in Spring 2016 (4 weeks) at lunch time.  
178  
18 They were clients of the Institut Paul Bocuse Experimental Restaurant. Subjects were not submitted  
1979 to a screener when they booked. Upon arrival, volunteers signed a consent form agreeing to  
20  
21 to a screener when they booked. Upon arrival, volunteers signed a consent form agreeing to  
2280 participate in a research study and being filmed during their meal. No reward was provided for  
23  
2481 participation, however, the experimental restaurant charges low fees with respect to the culinary  
25  
2682 quality and the quality of service provided.  
27  
28  
283

30  
3184 The videos of 118 people were coded. The non-coded videos correspond to subjects who were either  
32  
33 minors, foreigners, part of the Institut Paul Bocuse staff, who didn't consume bread at all during the  
3485 meal (e.g. coeliac disease), or whose angle of filming did not allow to see precisely all gestures.  
35  
3686 Moreover, an additional 18 subjects were excluded because they shared their dishes with other  
37  
38  
387 subjects. In total 100 participants were included in the analysis.  
40  
4188

## 42 43 4489 45 46 2.4. Procedure 47

### 48 2.4.1. Self-administered questionnaires 49

50 Upon their arrival, clients had to answer a small questionnaire about their hunger level (9 points  
5192 scale), their thirst level (9 points scale) and their current mood (CATA). A second questionnaire was  
52  
5393 distributed once the main dish and the bread basket and leftovers were removed from the table. It  
54  
5594 was constituted of three parts: the appreciation of the dishes, the bread and the wine (if applicable) (9  
56  
57  
5895

196 points scales), the bread consumption habits (moments of consumption, amount) and the socio-  
1  
197 demographic characteristics of participants.

#### 198 2.4.2. Videos

199 The Experimental restaurant was equipped with six cameras (SONY EVI-D70) fixed on the ceiling  
200 and distributed at different places of the room. Each camera is adjustable in a very precise way. Five  
201 cameras are placed above five different tables (table max capacity = 2-4 people), and the 6<sup>th</sup> camera  
202 shows the entire room. Every day, between 12 and 20 participants were filmed. Each recording  
203 started when the clients took place at the table and stopped when the 2<sup>nd</sup> questionnaire was  
204 distributed, i.e. after the main dish was consumed and before the dessert. Altogether, nearly 120  
205 hours of videos were collected for the experiment.

### 206 2.5. Products

#### 207 2.5.1. Meal

208 A typical, everyday French meal consists of a succession of two to four dishes. During the period of  
209 the test, the lunch menu at the experimental restaurant was composed of a fixed appetizer, a starter  
210 among three possible options, the main course among three possible options, and a dessert among  
211 three possible options (meal duration  $\approx$  1 hour). In Figure 1 the pictures of the different dishes are  
212 reported (as starters: a= quail egg, b= lamb's sweetbread, c= salmon; as main courses: d=bass, e=  
213 pork hock, f= poultry). The dishes varied in multiple visual, olfactive, textural, taste and flavour  
214 attributes with no systematic design. Some salient characteristics may be noted: the quail eggs, pig  
215 hock and poultry consisted of solid elements, the lamb's sweetbreads included a semi-solid puree,  
216 the salmon was rich in flavor and texture, and the bass featured a liquid sauce (Figure 1).  
217 Importantly, dishes were not selected individually but prepared in a balanced number and randomly  
218 assigned to the participants by the waiters, across and within tables. Participants were able to  
219 exchange a dish with their co-eaters before consumption, although this was rarely observed. Cases of

221 exchanging or sharing dishes after starting eating were not included in the data material (18  
1 occurrences). Each plate was eaten by the same number of people (30-33).

### Figure 1

#### 225 2.5.2. Bread

226 The bread was a high-quality frozen bread from fine white flour. Each bread serving had the form of  
13 a small baguette and weighed 40 g (+/- 1.3 g). Its constant weight allowed to estimate precisely the  
14 amount of bread eaten from the video footage. Bread was available *ad libitum* from the guests'  
15 arrival at the table and until clearance of the table after the main course.  
16  
17  
18  
19  
20

#### 231 2.6. Coding of the videos

232 Each video was manually coded with The Observer XT software (Noldus, The Netherlands). It  
233 allows translating qualitative data (film) to quantified data (time, duration, frequency). During the  
30 coding one differentiates between so-called state events, which drag in time, and point events, which  
31 are brief and punctual. Point events can occur simultaneously to state events, but not simultaneously  
32 to one another. Different kinds of actions were coded as presented in Table 1: meal phases (waiting  
33 time, appetizer, starter and main dish, coded as state events) which highlight the frame for the meal  
34 structure, bread actions (point events, see below), and consumption (placing food, bread or drink in  
35 mouth, originally point events in nature but coded into last-item-in-mouth state events, see  
36 explanation below). Thus, the three consumption point events (food, bread or drink) are transformed  
37 into one state event (last item in mouth) varying in four modalities (eating food/eating  
38 bread/drinking/nothing). Sub-actions were defined after video recording, pre-watching a few videos  
39 and also based on a previous paper (Iborra et al., 2018). The manual coding for each subject took  
40 between 45 minutes and 1 hour, approximately 12 days of coding for 100 subjects.

41 The use of bread was made up of five sub-actions: no interaction with bread; bread-mouth action;  
42 bread-hand action; bread-plate action; bread-cutlery action). All videos were coded by the same

247 experimenter. Twelve videos (10% of total recordings) were coded a second time by a second  
1  
248 experimenter for validation. The comparison was based on frequency/sequence of each action and  
3  
4  
249 state event, with a tolerance window of 10s. The agreement rate was 98.3 %.

33

34

35

36

37

38

39

40

41

42

43

44

45

Presenting results in the form of videos is not practical; it is also inappropriate for representing multiple events across time and consumers. On the other hand, presenting temporal data in the form of frequency counts loses the sequential information of events; for example, do consumers typically eat bread before the food or together with the food? To give a visual overview of the behavior of all consumers during the meal, TDBs were designed inspired by the principles of graphical representations used in the TDS and T-CATA methods for dynamic sensory curves (Pineau & Schlich, 2015; Castura, Antúnez, Giménez, & Ares, 2016). The principle in TDS and T-CATA graphs is that each curve represents a sensory attribute, and displays how this attribute evolves in time between occurrence and non-occurrence episodes throughout a food or drink consumption event. The curve is reported for several subjects, where the higher the proportion of subjects who perceive the attribute, the higher the curve, potentially reaching significance level. The principle in TDB is that each curve symbolizes a behavior of interest (instead of a sensory attribute) and thus to visualize the proportion of subjects performing this behavior at any time during the meal. In this way, we can reveal dominant actions, i.e. the actions most typically performed by consumers during the different phases of the meal.

46

47

48

49

50

51

52

53

54

55

As the majority of actions during the meal are brief events, the probability that several subjects have performed the same action simultaneously is very low. For example, even if all consumers were to consume some bread before receiving the food, they would not all place the piece of bread in their mouth at the same time-point of the video footage (point event), preventing the accumulative

56

57

58

59

273 proportions required to visualise this action as dominant in the TDB graph. To overcome this issue,  
1  
274 we coded the food intake data (drink, food and bread) as last-item-in-mouth state events and a TDS-  
3  
4  
275 like dataset was created (time discretization 1 second). That is to say that for example attribute  
6  
276 “food” would remain active from the moment the subject places food in their mouth, until another  
8  
9  
277 item (bread or drink) enters the mouth, in the same way as in TDS curves a sensory attribute remains  
10  
11  
278 active until another one is selected. Thus, the signal we are modelling is similar to a TDS sequence,  
13  
14  
279 replacing the sensory attributes by the modalities of the state event, the products being the starters  
15  
16  
280 and main courses. Note that the TDB approach is closer to TDS than to TCATA, because the  
18  
19  
281 modalities of the state events are exclusive. Note also that a modality “nothing” is utilised.  
20  
21  
282 To assess the effect of dish characteristics on what consumers eat at a specific moment, both for  
23  
283 starter and main dish, the food intake data for each subject was considered in the following time  
25  
26  
284 range: from when the dish was put on the table until it was removed. Meal phase duration was left-  
27  
28  
285 standardised across subjects. Data were reported as the percentage of subjects that performed each  
30  
31  
286 action over time including the chance level ( $p_c=0.33$ ) and the significance level ( $p_s$ =from 0.46 to 0.47  
32  
33  
287 depending on the dish) ( $\alpha=0.05$ ) (Pineau, & Schilch, 2015). A TDB graph was built for each type of  
35  
36  
288 dish.  
37  
38  
289 With a focus on starter dishes, each bread action was investigated in terms of percentage of subjects,  
40  
41  
290 the percentage of time occurrences and average duration. The percentage of subjects corresponded to  
42  
43  
291 the number of subjects that performed at least one time that bread action divided by the total number  
45  
46  
292 of subjects, reported in each hundred. The percentage of time occurrences was calculated by dividing  
47  
48  
293 the duration of that bread action by the total bread actions time, reported in each hundred. Finally,  
49  
50  
294 the average duration was calculated as the sum duration of that bread action divided by the number  
52  
53  
295 of times that it was performed. A two-way (type of action and dish type) ANOVA was performed on  
54  
55  
296 duration of each action. A multiple comparison analysis (Duncan’s test) was also performed, when  
57  
58  
297 necessary.  
59

60 All calculations were conducted in XLSTAT vers. 2010 (Addinsoft, France).  
61

299 **2.7.2. Consumer segmentation**

1  
300 To study the inter-individual differences in the use of bread during the meal, the subjects were  
3  
4  
301 segmented by Agglomerative hierarchical clustering analysis (AHC) according to two criteria: the  
6  
302 amount of bread consumed and the frequency of different bread interactions (bread-hand, bread-  
8  
303 cutlery, bread-plate and bread-mouth). A centring and reduction of the data was applied before  
10  
304 clustering (XLSTAT vers. 2010). AHC was performed by choosing the Euclidean distance for  
13  
305 dissimilarities and Ward's method as an agglomeration method. Entropy truncation was chosen as  
15  
306 criteria to determinate cluster numbers.

18  
307 **2.7.3. Group characterisation**

20  
21  
308 To characterize the different consumer groups in terms of socio-demographic, habitual and  
23  
309 behavioral characteristics a Partial Least Squares Discriminant Analysis (PLS-DA) model was built.  
25  
310 The model linked dependent variables for segment belonging (three binary variables with values 0/1)  
27  
311 to the questionnaire data (hunger level from the first questionnaire, and socio-demographics and  
30  
312 questions on consumer habits about bread, from the second questionnaire, respectively) and the  
32  
313 observational variables during the meal (bread quantity and bread actions) as independent variables.  
35  
314 All bread variables were log-transformed before analysis due to a high skewness in their distribution  
37  
315 (skewness range before/after transformation: 1.1 to 2.6 / -0.3 to 1.1). A first model was run with all  
40  
316 independent variables (i.e. 47 items), then was refined through variable selection based on a Jack-  
42  
317 knife uncertainty test with a 95% confidence interval (Martens & Martens, 2000). Cross-validation  
45  
318 with 20 random segments was used. The final model retains 12 independent variables and has a  
47  
319 variance fit of 50% with two PLS factors. The models were run in Unscrambler X 10.4.1 (Camo  
49  
320 Analytics, Norway).

52  
53 **2.7.4. Temporal Dominance of Behavior (TDB) of different groups**

54  
55  
322 For each consumer group a TDB graph was reported, allowing to compare group-specific curves  
57  
323 with the global TDB with all consumers. In this analysis, 4 different actions (nothing, eating,  
59  
324 drinking, bread action) were considered, so the chance level was reduced ( $p_c=0.25$ ) and the

325 significant level varied depending on the number of participants) ( $\alpha=0.05$ ). The evaluation time goes  
1  
326 from when the breadbasket was put on the table until it was removed, i.e. after the main course. In  
3  
327 this model, the total mealtime was not standardized as this did not bring any additional information.  
6  
328 It should be noted that the experimental restaurant operates at specific hours: it welcomes all booked  
8  
329 consumers at 12:30, serves all consumers relatively simultaneously, and closes after 90 minutes of  
10  
330 service (including dessert and coffee, not part of the data presented here). Meal durations were  
13  
331 therefore very similar across the different tables in this particular study.  
15

### 3. Results

#### 3.1. Characterization of the participants and consumption habits

334 The sample of filmed and coded subjects consists of 56% women and 44% men, aged 20 to 86 years  
23  
335 with an average of 45 years +/- 13 years. Managers / liberal professions (37%) and employees (33%)  
25  
336 are the most represented socio-professional categories, followed by retirees (13%). Their usual  
28  
337 consumption of bread most often takes place during dinner (69%) and at breakfast (64%). Bread is  
30  
338 reported to be mainly used to "taste the sauce" (84%) or as a support for another food (toast,  
31  
339 sandwich, cheese) (73%).  
35

#### 3.2. Temporal Dominance of Behavior (TDB) and bread actions for each dish

340 In Figure 2 is reported the percentage of subjects (%) who performed a specific action (eating,  
38  
341 drinking, bread interaction) over time, for each dish.  
40  
342

**Figure 2**

343  
45  
344  
47  
345 Similarly, for all dishes, i.e. both starters and main dishes, the first action was drinking.  
49  
50  
346 More specifically, for starters (Fig 2: a) quail egg; b) lamb's sweetbreads; c) salmon) there was no  
52  
347 particular difference among the dishes during eating. However, some differences appear at the end of  
53  
348 consumption, where bread actions were dominant for the lamb's sweetbreads which included a semi-  
54  
349 solid puree, and for the salmon which is rich in flavor and texture. Moreover, drinking was a  
55  
56  
57  
58  
59

350 dominant action for salmon. No dominance of bread actions was observed for the quail eggs dish,  
1  
351 which consisted of solid individual elements (Figure 1).

352 Looking at the three different main courses (Fig 2: d) bass; e) pork; f) poultry), differences among  
6  
353 the dishes appear in the eating phase, in terms of duration of dominance (shorter eating dominance  
8  
354 for the bass). In the final part, drinking was the dominant action for the three recipes, while bread  
10  
355 actions were dominant only for short periods and only for one dish, the bass, which featured liquid  
13  
356 sauce (Figure 1).

357 To deepen the contrasting differences of bread actions, consumer behaviors were analyzed in more  
18  
358 details during consumption. Results for the starters are reported in Figure 3.

### Figure 3

359  
360  
361  
362 During starter consumption, the bread actions performed by almost all the consumers were “cutting”  
30  
363 (>95%), followed by “piece of bread” (i.e. eating a piece of bread, >85%), ”with sauce” (i.e. eating  
32  
364 bread with sauce) and “saucing” (i.e. absorbing sauce from the plate on a piece of bread) (Figure 3a).

365 Those two final actions were performed by a different percentage of subjects depending on the type  
37  
366 of starter, highest for lamb’s sweetbread, medium for salmon and lowest for quail egg.

367 The most performed bread actions, calculated as the time percentage of each action on the total time,  
42  
368 were two bread-mouth actions, ”piece of bread” (45%), ”with sauce” (20-25%), followed by  
44  
369 ”cutting” (15-20%), with no particular differences among the different starters (Figure 3b).

370 As expected, bread actions presented significant different durations, varying from 10 s for ”cutting”  
49  
371 to 20-25 s for “piece of bread” (p=0.03). Analysis of variance showed that there was an effect of the  
52  
372 dish only on the duration of 3 (one bread-plate and two bread-mouth actions) out of 14 bread-actions:  
54  
373 “pushing” (p=0.03), “with sauce” (p= 0.023) and “with bread” (p=0.04). In particular, a significant  
57  
374 longer duration of the actions ”with food” and ”with sauce” was found for salmon compared to quail  
59  
375 egg and lamb, meanwhile “pushing” lasted more for quail egg than other plates.

376 3.3. Consumer segmentation

1  
377 The quantity of consumed bread (from 10 to 180 g, mean  $60\pm 34.5$  S.D), the number of bread-hand  
3  
378 (from 3 to 56, mean  $17.6\pm 11.1$  S.D), bread-cutlery (from 0 to 10, mean  $1.1\pm 1.8$  S.D), bread-plate  
4  
5  
6  
379 (from 0 to 42, mean  $7.5\pm 6.9$  S.D) and bread-mouth (from 4 to 69, mean  $22.5\pm 12.9$  S.D) actions all  
7  
8  
9  
380 varied very much among consumers, allowing to split consumers into different groups with AHC.  
10  
11  
381 Three groups were formed, with a within-class variance of 36% and between-class variance of 64%.  
12  
13  
382 The first group was composed of 43 subjects (Centroid object characteristics: quantity of consumed  
14  
15  
383 bread= 38.1g, bread-hand actions= 10, bread-cutlery= 0.2; bread-plate= 3.5; bread-mouth= 13.3), the  
16  
17  
384 second group of 48 subjects (Centroid object characteristics: quantity of consumed bread= 69.8 g,  
18  
19  
20  
21  
22  
23  
385 bread-hand actions= 21.2, bread-cutlery= 1.9; bread-plate= 10.7; bread-mouth= 26.9) and the last  
24  
25  
386 one of only 9 subjects (Centroid object characteristics: quantity of consumed bread= 133.3 g, bread-  
26  
27  
387 hand actions= 40.8, bread-cutlery= 1.9; bread-plate= 13.9; bread-mouth= 40.8).

28  
288 3.4. Group characterisation

29  
30  
31  
389 In figure 4 the score plot of the PLS-DA model was reported, where the three groups from AHC  
32  
33  
390 were highlighted. This graph testifies of a rather clear distinction between the three groups with two  
34  
35  
36  
391 latent factors (Y-explained variance 50%). Group 3 may be seen as an extreme subgroup of group 2,  
37  
38  
392 with the highest scores on factor 1 (characterising higher bread quantity and more bread actions,  
39  
40  
41  
393 result not shown) and a reduced spread along with factor 2 (characterising socio-demographics and  
42  
43  
394 bread motives, not shown).

44  
45  
46  
47  
48  
49

60  
61  
62  
63  
64  
65  
**Figure 4**

53  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65  
The group characterisation by PLS-DA approach revealed 12 significant variables in the differentiation of groups: the level of hunger before the restaurant meal, the five bread-related variables collected during the meal (bread quantity and bread-hand, bread-cutlery, bread-plate and bread-mouth actions), as well as consumption of wine during the meal; questionnaire variables on

402 stated bread consumption (never eats bread), stated motivations of bread consumption (to occupy  
1 waiting time, to sate hunger) and socio-demographic variables age and retired occupation (Figure 5).

### 405 **Figure 5**

406  
11  
407 Group 1 (43 %) may be called the “No-breaders”: it was composed of individuals who stated rarely  
13  
14  
408 eating bread and who indeed consumed little bread during the restaurant meal (mean consumption:  
15  
16  
409 40 g, i.e. one bread unit). They interacted little with bread altogether during the restaurant meal.  
18  
19  
410 These consumers also rarely ordered wine during the meal and tended to be younger. Consumers in  
20  
21  
411 Group 2 (48 %), the “Bread-as-a-tool” group, consumed a fair amount of bread during the restaurant  
23  
24  
412 meal (mean consumption: 70 g) and interacted with bread in particular with their plate and cutlery,  
25  
26  
413 allowing them to consume sauce and to “clean” the cutlery. These consumers most typically  
27  
28  
414 consumed wine with their meal; they were also typically older and had retired from their professional  
30  
31  
415 occupation. Last, Group 3 (9%) may be referred to as the “Bread-lovers”: this group consumed the  
32  
33  
416 biggest amount of bread (mean consumption: 130 g) and their bread interactions were dominated  
35  
36  
417 with hand-bread and mouth-bread actions. They reported a higher level of hunger before the  
37  
38  
418 restaurant meal, which may explain their higher consumption. However, rather than a random  
40  
41  
419 occurrence, their high bread consumption seems to be a stable trait as this group also stated to  
42  
43  
420 typically use bread to sate hunger and to occupy waiting time during a meal. This group tended to be  
45  
46  
421 older than Group 1, yet still in professional activity.

### 422 423 3.5. Temporal Dominance of Behavior (TDB) of different groups

424 A typical French meal at the restaurant consists of an appetizer (A), followed by a starter (ST), a  
425 main course (MC) and a dessert (the latter is not inserted in the analysis as it is not consumed with  
426 bread). The duration of the meal was about 3600s and was divided into six different phases: 3  
427 waiting times (W1-3) before each dish, and three eating phases (A, ST, and MC). In Figure 6 the

428 Temporal Dominance of Behavior (TDB) give a graphical representation of consumers' eating  
1  
429 behavior during the meal, by reporting the percentage of subjects that performed each action over  
3  
430 mealtime. The four main actions in focus were: no action, bread action, eating and drinking. Figure  
4  
5  
6  
431 6a reports results for all participants, while Figures 6b-c-d report results for the three consumer  
8  
9  
432 groups defined with AHC.

### Figure 6

14  
15  
16  
435 Looking at the global TDB (Figure 6a), during the first waiting period (W1), the dominant actions  
18  
19  
436 were *no action* from the beginning to the half of the time followed by *drinking*. During the appetizer  
20  
21  
437 phase (A), three actions were dominant: *drinking*, *eating* and *bread action* (only during the last part),  
23  
24  
438 and the most dominant one for a long time was *eating* with a consumer percentage varying from 40  
25  
26  
439 to 60%. During the second waiting period (W2) both *drinking* and *bread action* were dominant, even  
27  
28  
440 if *drinking* was the most dominant action. During the starter consumption phase (S), the most  
30  
31  
441 dominant action was *eating*, for a long time, and only at the end of this phase two other actions were  
32  
33  
442 dominant, *bread action* and *drinking*. During the third waiting phase (W3), the most dominant action  
35  
36  
443 was *bread action* at the beginning followed by *drinking* for the biggest time. Finally, during the main  
37  
38  
444 course consumption phase (MC), *eating* was the most dominant action, with a very high consumer  
40  
41  
445 percentage, and only during the last minutes both *drinking* and *bread actions* were dominant with a  
42  
43  
446 comparable consumer percentage.

45  
46  
447 Looking at the consumer behavior of No-breaders (Group 1) reported in Figure 6b, it appears that  
47  
48  
448 bread action was never dominant during the mealtime, with an exception at the end of the starter  
49  
50  
449 phase. However, when No-breaders were waiting for a dish they preferred drinking than consuming  
52  
53  
450 bread.

54  
55  
451 For what concerns the Bread-as-a-tool group (Group 2), their behavior resembled that of No-breaders  
57  
58  
452 from the beginning to the W2 phase, during which bread action was never dominant. Meanwhile,  
59  
60  
453 during the end of the S phase, bread action became dominant and was also the most dominant action

454 for a short time. During the W3 phase, bread action was the most dominant action with a consumer  
1  
455 percentage of 40-50%, then, drinking was the most dominant action, even if bread action was still  
3  
456 above the significance threshold.  
4  
5  
6

457 Consumer behavior of Bread lovers (Group 3) was completely different compared to the other two  
8  
458 groups (Figure 6d). For those consumers, bread action was dominant not only during the waiting

For those consumers, bread actions were performed during all the mealtime.

## 4. Discussion

### 4.1 Data acquisition and video data coding

The reported results were obtained at a living lab, in a restaurant with the booking done on the internet. No detailed information about the meal or the purpose of the study was known by the participants, who were coming to the restaurant to enjoy a meal with friends, colleagues and/or family and not to participate in a research study. This process guarantees natural eating conditions. However, it does not allow specific recruitment which led to the exclusion of about a quarter of the visitors (minors and subjects not consuming bread) who were filmed but not coded. Moreover, in a real consumption situation, customers act normally, so certain parameters varied greatly from one table to another or within the same table and could not be controlled, such as meal phases duration and waiting times, or the fact that subjects at the same table sometimes exchanged their dishes – leading to additional subject exclusions from the analysis. During a laboratory experiment, participants can be selected, several parameters can be controlled, but participants may tend to act differently from a natural eating condition, e.g. they may decrease their food/beverage intake if they believe that the amount of food they are eating during a study is being monitored (Robinson, 2014). Despite the advantages of having a natural situation, this condition caused data loss and a greater variability which requires greater sample sizes.

479 A limitation of the living lab is that some participants may remain aware of the cameras and refrain  
1  
480 behaviours that may be considered socially inadequate (e.g. saucing their plate with a piece of  
3  
481 bread). However, cameras may not be interfering more than public exposure to other clients and  
4  
6  
482 personnel in the restaurant. On the opposite, we expect people are better able to forget about the  
8  
9  
483 cameras and act naturally during a meal at the restaurant with friends or colleagues, than in an  
10  
11  
484 experimental lab. Further, a video for each consumer was recorded and coded. How to codify  
13  
14  
485 consumer behavior and report consumers' actions based on video observations is a big issue. Videos  
15  
16  
486 contain a very large amount of codable information and should be codified following the aim of the  
18  
19  
487 study. Several studies based on video observation have been interested in measuring eating behavior  
20  
21  
488 in terms of meal microstructure, relying either on manual count (or, more recently, on automatic  
23  
24  
489 detection) of bites, chews, and swallows (Fontana et al., 2015; Hossain, Ghosh, & Sazonov, 2020).  
25  
26  
490 Other studies have described a meal event at the microstructure level by adopting a qualitative  
27  
28  
491 approach to data analysis supported with numerical counts of particular events (see e.g. Liu et al.,  
30  
31  
492 2019). In the present application, the meal macrostructure is in focus with a particular interest on  
33  
34  
493 consumers' bread interactions during a meal. Consequently, the coding frame we developed shed  
35  
36  
494 light on all bread-related behaviors. One may imagine a similar study focusing on social and digital  
37  
38  
495 interactions during a restaurant meal, in which case a very different set of actions would be coded  
40  
41  
496 from the same footage (e.g. conversation events with fellow eaters and with waiters, and/or  
42  
43  
497 interactions with smart phones). A limitation of the manual coding method is the duration of video  
45  
46  
498 coding, because it takes between 45 minutes and 1 hour of coding per subject, approximately 12 days  
47  
48  
499 of coding for 100 subjects. One may hope that in the future artificial intelligence algorithms will be  
49  
50  
500 utilised in video coding software, to able to automatically recognise specific patterns in a video such  
52  
53  
501 as putting a piece of bread in the mouth or taking a sip of water.  
54  
55  
502 As reported in material and methods, different kinds of actions were coded. Meal phases and last-  
57  
58  
503 item-in-mouth were coded as state events, whereas use of bread, food and beverage were coded as  
59  
60  
504 point events. However in the case of bread usage, that is the core of this paper, some actions were

505 quite long (for example, "cleaning the plate with the bread" or "playing with a piece of bread") and to  
1  
506 consider them as a point events leads to some loss of information.

#### 507 4.2 Temporal Dominance of Behavior (TDB)

508 Behavioral data are dynamic data, so after the coding, the quantitative data could be represented  
8  
509 using dynamic methods. The TDB approach that we proposed makes it possible to summarize hours  
10  
510 of video in a single graph. This visualisation gives an overview of consumer behavior during the  
13  
511 meal or for a meal phase, reporting the sequence of these behaviors as dominant actions over time.

512 This approach seems promising and could be of great help in observational studies of consumer  
18  
513 behavior.

514 The videos of this study could for example also be used to study the consumption of drinks during  
23  
515 the meal, the behavior of consumers towards wine, the consumption strategy of a dish (proteins first,  
25  
516 vegetables first, or both together), but also the use of digital objects at the table (telephone,  
28  
517 camera...), or the occupations of the subjects during the waiting phases. Of course, this list is not  
30  
518 exhaustive and when this method is developed, it can be used to exploit observation data by  
32  
519 researchers from many disciplines, whether in food science, social science or economical science.

520 Despite these prospects, some limitations came out. TDS curves are normally used to represent  
37  
521 sensory descriptive data over periods of a few seconds whereas here, the data is behavioural and of  
40  
522 the order of the hour. The probability that different consumers doing the same thing (e.g. taking a sip

523 of water) would do this at the same time point is extremely low, and our preliminary analyses did not

524 succeed in capturing cumulative behaviours of such brief actions. We addressed the issue by coding

525 eating/drinking behavior as 'last thing in mouth'. In this way, the curves of all consumers taking a

526 sip of water in the period between two dishes may nicely cumulate; consequently, the duration of

527 some actions could be strongly sur-estimated. If a subject consumes bread only once at the start of

528 the waiting phase and does not consume anything until the arrival of the dish, he will be considered

529 as eating bread during the whole waiting phase. Thus, our present coding highlights *what* consumers

530 do in different parts of the meal rather than *for how long* they do it. One possible solution could be to

531 code the attribute "Nothing" as the last thing in the mouth either when there is a change in phase of  
1  
532 the meal, or after a certain time without new food intake, similarly to a TCATA Fading approach  
3  
533 (Ares et al., 2016).  
5

534 A second issue is to decide if the standardization of data should be performed or not. To report  
8  
535 consumer actions for different dishes, a time standardization was performed to align the meal phase  
10  
536 times across consumers. This standardization may however be questionable, as it can be assumed  
13  
537 that consumer behavior varies according to the actual phase duration. In particular, comparing the  
14  
538 behavior of a consumer with low waiting time before the food arrives to the behavior of a consumer  
16  
539 with longer waiting time may be biased, as the latter has more time to drink and interact with bread  
20  
540 in the waiting phase. A standardisation per meal phase could in this case be recommended (Lesme et  
21  
541 al, 2020). Further, to report the actions of different consumer groups over the whole meal, no time  
25  
542 standardisation was applied. Yet standardisation could favour a more systematic comparison of  
26  
543 frequencies and relative durations of actions during a particular meal phase. In this specific  
30  
544 application, the absence of standardisation was acceptable as limited variation occurred in meal  
31  
545 duration at the experimental lunch restaurant. Analysis at a lower level (per dish) may be more  
33  
546 sensitive to standardisation. It is also possible that the segmentation led to a stronger coherence  
36  
547 within each TDB. Further, one may consider decomposing single dishes into several periods, to  
38  
548 better analyse dish-specific bread interactions at a micro-level. This approach may be especially  
42  
549 interesting in combination with an experimental design, varying specific properties of the dishes  
43  
550 systematically. Further methodological developments are needed to handle time standardisation for  
47  
551 behavioral observation studies that stretch over time.  
48

50  
552 In summary, the concept we present here offers new opportunities, but also calls for further  
52  
553 developments in line with the specificities of observational data. Among other, one may refine video  
53  
554 coding strategies, highlight difference curves (Pineau et al 2009), optimise time standardization  
57  
555 (Lenfant et al, 2009, Lesme et al, 2020), use data temporality in consumer segmentation (Cardot et

556 al, 2019), or explore other time-based statistical approaches (Kuesten, Bi, & Feng, 2013; Esmerino et  
1  
557 al., 2017).

558

#### 559 4.3 Bread behavior

560 The consumption of bread is a complex phenomenon and our study shows that it may vary according  
10  
561 to individual preferences and characteristics, satiety level and type of dishes. In the French culture,  
11  
562 bread is often consumed as an accompaniment to the food and its consumption will vary with the  
12  
563 sensory characteristics, especially the textural characteristics, of the dish. Thus our study expectedly  
13  
564 highlights that bread consumption increases with the fluidity of the dish, where the starter presenting  
14  
565 sauce (lamb's sweetbread) led to more bread consumption than the starter including a puree (salmon)  
15  
566 or the starter presenting solid elements only (quail egg). This may be an important aspect to consider  
16  
567 in the food hospitality service for composing balanced menus. Our results also showed that the dish  
17  
568 composition seems to affect both on the dominant actions over the meal and the type of bread  
18  
569 actions. Experimental design on the ratio of liquid/semi-liquid components in the meal could be  
19  
570 helpful to further study the role of culinary characteristics of the dish on bread consumption. Another  
20  
571 opening for future research could be the characteristics of the bread itself: e.g. whether it is more or  
21  
572 less soft, crunchy, high in the aroma as well as liking score.

573 Further, we drafted consumer profiles for three consumer groups, underlining relationships between  
22  
574 consumer characteristics and their eating behavior during the meal. The clustering method identified  
23  
575 that there are different consumer groups according to bread usage. The PLS-DA model revealed that  
24  
576 besides the type of dish, individual habits and preferences strongly drive the motivation for bread  
25  
577 consumption, the bread quantity consumed during a meal and the type of interactions with bread.  
26  
578 While some consumers had little interest for bread (No-breaders, 43%), others used it primarily as an  
27  
579 eating utensil (Bread-as-a-tool group, 48%) and others again substantially fed on it (Bread lovers,  
28  
580 9%). Looking at the bread-related behavior of each consumer group, the main differences laid during  
29  
581 the waiting phases (W1-W2-W3), because, as expected, eating was often the most dominant action

582 whenever consumers were eating the appetizer, starter and main course. Future research may further  
1  
583 investigate the role of individual characteristics and eating speed versus hunger level and dish  
2  
3  
4  
584 composition on bread consumption. One may also segment consumers within products, to highlight  
5  
6  
585 food-specific behaviours. Moreover, in this study, the subjects' occupations during waiting times  
7  
8  
586 have not been coded (talking, using their phone, reading the menu, etc.). Future research may study  
9  
10  
587 the link between a subject's consumption of bread and their non-food-related behavior at the table  
11  
12  
588 (i.e. whether the subject speaks or listens during a conversation, whether he uses his phone, if he is  
13  
14  
589 playing with his cutlery or if he seems to be bored) and the social influence of co-eaters on eating  
15  
16  
590 behaviour.

## 5. Conclusion

592 This paper presents a novel approach to summarize, visualise and ease the interpretation of video  
593 observation data, the Temporal Dominance of Behavior (TDB). We applied the approach on video  
594 observations from 100 guests at a living lab restaurant, with a focus on bread consumption  
595 throughout a three-course lunch meal. The TDB approach provides a dynamic graphical synthesis of  
596 the subjects' eating behavior. By investigating not only the frequency of events but also their  
597 sequence, simultaneity and dominance, one may reach greater insights in consumer behavior. Future  
598 methodological developments are recommended to address the issues of treating punctual events and  
599 of time standardisation. The analysis of bread consumption behavior highlighted strong individual  
600 variations in terms of quantity as well as in terms of bread interactions during a meal, in part linked  
601 to textural differences in the different dishes. Three consumer groups differing in bread-related  
602 behavior throughout the meal were identified, profiled and characterized with the TDB approach.  
603 Future studies may further investigate the role of individual differences, dish composition and bread  
604 properties on bread consumption patterns during a meal.

## 607 Acknowledgements

608 The authors are grateful to the staff in the restaurant, especially the chefs Volckaert and l'Hospitalier  
1  
609 and the headwaiter Xavier Gonet, for their kind collaboration in this study. Anne-Cécile Brit is  
3  
610 thanked for technical support and instructions with operating the cameras and for validity checks on  
4  
611 the coding of the videos. Special thanks to MSc student Manon Lagnado-Léger from AgroParisTech  
5  
612 for her contributions in planning and conducting the study, for the video codings, and for preliminary  
6  
613 data analyzes from this study. Formerly BSc student Pauline Barbier is thanked for her collaboration  
7  
614 in a feasibility study which tested the concept of the TDB approach. Author V.L.A. acknowledges

773 **Table 1.** Coding frame of the meal structure and behavioral actions of interest.

	<b>Categories</b>	<b>Subcategories</b>
<b>State events</b>		
Meal phases	<i>Waiting time</i> Appetizer Starter	Quail egg Lamb's sweetbreads Salmon
	Main course	Bass Pork hock Poultry
Last item in mouth	<i>Nothing</i> Drink Food Bread	
<b>Point events</b>		
Bread interactions	<i>No bread interaction</i> Bread-mouth action	Piece of bread (alone) (Piece of bread) With food (Piece of bread) With sauce Crumb Biting
	Bread-hand actions	Cutting Touching/Playing (Taking) from the (bread) basket
	Bread-plate actions	Saucing Pushing food Spreading
	Bread-cutlery actions	Cleaning the knife Cleaning the fork Jabbing with the fork

*Italics* indicate default setting upon start.

777 **Figure captions**

778 **Figure 1.** Pictures of the starters (a-b-c) and main courses (d-e-f)

3  
779 a= quail egg; b= lamb’s sweetbreads; c= salmon; d=bass; e= pig hock ; f= poultry

6  
780 **Figure 2.** Temporal Dominance of Behavior (TDB) during starter (a-b-c) and main course (d-e-f)  
8  
781 consumption

11  
782 ——— drinking; ——— bread action; ——— eating;  
12  
783 - - - - - chance level (p<sub>c</sub>); - - - - - significance level (p<sub>s</sub>)

14  
784 **Figure 3.** Bread interactions during starter consumption for each starter

16  
785 a= Percentage of participants (%) that performed each action; b= Percentage of occurrence of each bread  
18  
786 action; c= Mean duration of single bread action (s) and standard error

20  
21  
787 3 Starters: ■= quail egg (31 subjects); ■= lamb’s sweetbreads (32 subjects); ■= lmon (32 subjects)

24  
788 For each bread interaction action, at different letters correspond significant different durations (Duncan’s test  
26  
789 p<0.05)

28  
29  
790 **Figure 4.** PLS-DA scores plot of the three consumer groups

31  
32  
791 **Figure 5.** Significant group characteristics for a) group 1, b) group 2, and c) group 3 from PLS-DA

34  
792 Regression coefficients with confidence intervals crossing the 0 line are not significant for that specific group.

36  
37  
793 **Figure 6.** Temporal Dominance of Behavior during meal of all subjects (a) and for different subject  
39  
794 groups according to bread interaction (b-c-d)

41  
42  
795 a= all subjects (100); b= group 1 (48 subjects), “No-breaders”; c= group 2 (43 subjects) “Bread-as-a-tool”; d=  
43  
796 group 3 (9 subjects) “Bread lovers”

45  
797 Different actions: ——— no action; ——— drinking; ——— bread action; ——— eating  
46  
798 - - - - - chance level (p<sub>c</sub>); - - - - - significance level (p<sub>s</sub>)

48  
49  
799 W1= First waiting time, before appetizer; W2= Second waiting time before starter; W3= Third waiting time  
50  
800 before main course; AP=appetizer; S=starter; MC=main course

## **Author declarations**

The authors declare that they do not have any conflict of interest.

The authors declare that the study was conducted according to the guidelines laid down in the Declaration of Helsinki and General Data Protection Regulation (GDPR), and was approved by the Research Protocol Committee of Institut Paul Bocuse according to national ethics guidelines (Loi Jardé, n 2012-300, 12 March 2012).

Written informed consent was obtained from all consumers before their participation in the study, including a video recording consent form.
