60
61
62 **10 Abstract**
63
64

65 11 Expectations of satiation and satiety have been increasingly investigated because of
66
67 12 the interest in how they, along with liking, can modulate portion-size selection.
68
69 13 Consumer characteristics can also be important when consumers select their portion
70
71 14 size. However, the contribution and interaction of consumers and product aspects to
72
73 15 portion size selection has not been unveiled. This study aims to better understanding
74
75 16 these complex relations by simultaneously assessing the relative influence of
76
77 17 consumer characteristics and product related properties on portion size selection
78
79 18 utilizing PLS-Path Modelling (PLS-PM) approach.
80
81
82

83 19 In this study, consumers (n=101) answered questions regarding attitudes to health and
84
85 20 hedonic characteristics of foods, and completed hunger and fullness questions. In an
86
87 21 evaluation step, they tasted eight samples of yogurt with different textures and rated
88
89 22 liking, expected satiation, expected satiety and portion size. The consumers were also
90
91 23 classified on their mouth behaviour by using the JBMB™ tool.
92
93

94 24 Results showed that *liking*, *satiation*, *satiety* and *portion size* depended firstly on the
95
96 25 thickness, and then on the particle size of samples. PLS-PM was used to generate a
97
98 26 model, indicating that *liking* was a direct predictor of *portion size*, with a stronger effect
99
100 27 than *satiation* or *satiety*. The relationship between *liking* and *satiety* was observed both
101
102 28 in direct direction (*liking-satiety*) and also indirect direction throughout *satiation* (*liking-*
103
104 29 *satiation-satiety*). The former was negative effect and the latter was positive effect
105
106 30 depending on the criteria which consumers used.
107
108

109
110 31 These findings implied that *liking* is a main factor in the prediction of *portion size*
111
112 32 however the relations are complex.

35

178
179
180 **36 1. Introduction**
181

182
183 **37 *Satiation, satiety and consumers' expectations***
184

185
186 **38** Until now, many studies of meal size have indicated that when deciding on a
187
188 **39** particular portion size, our strategy may be guided by a concern to ensure that a portion
189
190 **40** of food will deliver adequate satiety (Brunstrom & Shakeshaft, 2009). Satiety
191
192 **41** comprises two processes: satiation (intra-meal satiety) and satiety (post-ingestive
193
194 **42** satiety or inter-meal satiety). The former is defined as the process that leads to the
195
196 **43** termination of eating; therefore, controls meal size. The latter is the process that leads
197
198 **44** to inhibition of further eating, decline in hunger, increase in fullness after a meal is
199
200 **45** finished (Blundell et al., 2010).
201
202

203
204 **46** Satiation is measured through the measurement of *ad libitum* food consumption of
205
206 **47** particular experimental foods (weight in grams or energy in kcal or kJ) under
207
208 **48** standardized conditions. Satiety is usually measured using a preload-test meal
209
210 **49** paradigm (Blundell et al., 2010). Expectations of satiation and satiety without
211
212 **50** consuming a whole portion, but relying on a prospective portion size (de Graaf, Stafleu,
213
214 **51** Staal, & Wijne, 1992; Fiszman & Tarrega, 2017), have been used to measure satiation
215
216 **52** and satiety in many studies.
217
218

219 **53** Brunstrom and colleagues have showed that people have very precise expectations
220
221 **54** about satiety and satiation that foods are likely to confer (Brunstrom & Rogers, 2009;
222
223 **55** Brunstrom & Shakeshaft, 2009; Brunstrom, Shakeshaft, & Scott-Samuel, 2008). In
224
225 **56** general, expected satiety can be quantified by asking the participant to select the
226
227 **57** amount that would be needed to stave off their hunger for a specific period of time,
228
229 **58** whereas expected satiation can be quantified by selecting the amount that would be
230
231 **59** required to feel full. Ideal portion-size can be assessed by asking the participant to

60 select the amount that they would typically consume or the amount that they would like
61 to consume at that moment (Wilkinson et al., 2012).

62 *Satiety-related perceptions and portion size selection*

63 Two foods of equal nutrient content may have different effects on appetite. This is
64 because aspects of food consumption, other than the metabolic effects of nutrients in
65 the gastrointestinal tract, contribute to processes involved in appetite control
66 (Chambers, 2016). The ‘Satiety Cascade’ (Blundell et al., 2010) describes that both
67 expected satiation and satiety of foods rely on sensory attributes of foods. Among
68 sensory dimensions, texture imparts expectations of satiation and satiety clearer than
69 flavour does (Chambers, 2016; Hogenkamp, Stafleu, Mars, Brunstrom, & de Graaf,
70 2011). Food texture can influence at several levels. First, texture plays a critical role in
71 satiation or satiety through its effect on oro-sensory exposure. Due to their fluid nature,
72 liquid foods require less oral processing time than semi-solid and solid foods, leading
73 to reduction in oro-sensory exposure, which is important for the development of satiety
74 related perceptions (McCrickerd, Chambers, Brunstrom, & Yeomans, 2012; Tang,
75 Larsen, Ferguson, & James, 2017). More specifically, longer mastication duration and
76 higher intensity of sensory signals are also linked to higher satiation (Blundell et al.,
77 2010; Bolhuis, Lakemond, de Wijk, Luning, & Graaf, 2011). Second, from a cognitive
78 perspective, people may think solid foods are more satiating than liquid foods, i.e. solid
79 foods will contain more energy than liquid foods, without necessarily reflecting their
80 actual calories (de Graaf, 2012).

81 *Palatability and portion size selection*

82 In addition to the expectations of satiation and satiety, palatability of food is seen as
83 an important determinant of portion size selection. The role of palatability in prediction
84 of portion size, however, has been debated over different studies. Some studies

85 indicated that reducing the palatability of our diet should result in reduced food
86 consumption (Yeomans, Blundell, & Leshem, 2004). Likewise, incremental increases
87 in palatability lead to short-term overconsumption; that is, we consume more of foods
88 that we like (Cooke & Wardle, 2005; Yeomans, 2007). Nevertheless, other studies
89 found that palatability was not associated with the selection of portions and then
90 rejected the hypothesis of these palatable foods tend to be selected in relatively larger
91 portions (Brunstrom & Rogers, 2009). Recently, the question whether “quality can
92 replace quantity” has been raised in some studies. It has been found that palatability
93 is unable by itself to predict people’s food behavior. Instead food reward, an immediate
94 sensation of wanting and liking a food when it is eaten and as a longer lasting feeling
95 of well-being after a meal, could be used to predict the behavior. Under the assumption
96 that well-tasting/high sensory quality foods provide more reward per energy unit than
97 bland foods, the hypothesis that ‘quality can replace quantity’ has been supported
98 (Møller, 2015a, 2015b).

99 It is important to note that expected satiation, satiety and hedonic quality influence
100 each other and together they influence portion size. Nevertheless, the ways in how
101 these expectations are related are still unclear; while some studies showed that if
102 people eat a food they greatly enjoy, they will experience more pleasure, satiation and
103 satiety (Bobroff & Kissileff, 1986; Mattes & Vickers, 2018; Rogers & Schutz, 1992),
104 others observed that increased liking decreased feelings of satiety or satiation (Hill,
105 Magson, & Blundell, 1984; Holt, Delargy, Lawton, & Blundell, 1999).

106 *Individual differences in consumer expectations*

107 Individual differences should be considered when evaluating the relations between
108 these expectations. Individuals use different mechanisms for the oral breakdown of
109 food so that at any point, different groups of individuals would experience the samples

355
356
357 110 differently (Brown & Braxton, 2000). The differences might have different impacts on
358
359 111 sensory perception, which in turn, would drive consumer expectations (i.e. liking,
360
361 112 expected satiation and satiety) (Jeltema, Beckley, & Vahalik, 2015, 2016). Individuals
362
363 113 have subjective experiences of satiety which are influenced more by what the person
364
365 114 saw and remembered, and less by what they actually ate (Brunstrom, 2014;
366
367 115 McCrickerd & Forde, 2016; Wilkinson & Brunstrom, 2009). These experiences should
368
369 116 be considered when determining the relations between consumer expectations.
370
371

372 117 The objective of this paper is to investigate and model from a holistic perspective
373
374 118 different aspects of consumer expectations (liking, satiation, satiety) using a PLS path
375
376 119 modelling approach. Our study differs from preceding studies in that we consider all
377
378 120 consumer expectations simultaneously in the prediction model. In addition, consumer
379
380 121 attitudes towards health and taste, experiences relevant for satiety and individual
381
382 122 differences were measured. Main attention will, however, here be given to the product
383
384 123 related measurements.
385
386

387 124 **2. Materials and methods**

388 125 *2.1. Samples*

389
390
391 126 Eight yoghurt samples were prepared from a design of experiment (DOE) based on
392
393 127 the same ingredients, only modifying the product texture by using different processing
394
395 128 strategies, so as the samples would have the same calories and composition and these
396
397 129 parameters would not influence satiety or satiation. The parameters of the DOE were:
398
399 130 viscosity (thin/thick), particle size (flake/flour) and flavour intensity (low/optimal); see
400
401 131 (Nguyen, Næs, & Varela, 2018) for details. Table 1 shows the samples with different
402
403 132 levels of viscosity, particle size and flavour intensity.
404
405
406
407
408
409

410 133 *2.2. Consumer test*

414
415
416 134 One hundred and one consumers were recruited for the test in the southeast area
417
418 135 of Oslo from Nofima's consumer database (73 females and 28 males, aged ranging
419
420 136 between 18 and 77). Participants were regular yoghurt consumers (at least once a
421
422 137 week). A recruitment questionnaire was used to collect general information (age,
423
424 138 gender, BMI, consumption and usage) and to select consumers based on consumption
425
426 139 frequency. Additionally, consumer attitudes were collected through the health and taste
427
428 140 questionnaire proposed by Roininen et al. (1999).

431
432 141 The formal assessment was performed in individual booths and had two parts. The
433
434 142 first part was about consumers characteristics: they answered items about hunger and
435
436 143 fullness question (Karalus & Vickers, 2016), and attitudes toward healthfulness of food
437
438 144 and toward taste (Roininen, Lahteenmaki, & Tuorila, 1999). The second part was about
439
440 145 product characteristics, consumers were asked to taste each sample and rate liking,
441
442 146 expected satiation, expected satiety, ideal portion-size, and to describe the samples
443
444 147 using Check All That Apply (CATA) questions (Adams, Williams, Lancaster, & Foley,
445
446 148 2007). During the CATA task, they were presented with the predefined list of attributes
447
448 149 and asked to indicate which words or phrases appropriately describe their experience
449
450 150 with the product being evaluated. The CATA question consisted of 22 sensory
451
452 151 attributes (*Vanilla, Sour, Oat flavour, Sweet, Cloying, Bitter, Fresh, Unfresh, Thick,*
453
454 152 *Gritty, Sandy, Dry, Creamy, Mouth coating, Chewy, Sticky, Dense, Smooth,*
455
456 153 *Heterogeneous, Homogeneous, Liquid, Pieces*) and 13 usage and attitude terms (*Easy*
457
458 154 *to swallow, Difficult to swallow, High calorie, Low calorie, Satiating, Not satiating,*
459
460 155 *Appealing, Not appealing, Suitable for breakfast, Suitable for snack, Suitable for*
461
462 156 *supper, Fibrous, Healthy*). The order of terms was randomized within the two groups
463
464 157 (sensory and usage), between products, and across assessors.

473
474
475 158 Regarding the scales used for the consumer test, the consumers rated liking on a
476
477 159 Labelled Affective Magnitude (LAM) scale (Schutz & Cardello, 2001), expected
478
479 160 satiation on a Satiety Labeled Intensity Magnitude (SLIM) scale (Cardello, Schutz,
480
481 161 Leshner, & Merrill, 2005) and expected satiety on a 6-point scale from 1 = “hungry again
482
483
484 162 at once” to 6 = “full for five hours or longer”. For ideal portion-size, they chose the
485
486 163 extent to which they would consume as compared to the normal amount of commercial
487
488 164 yoghurt product. The portion-size scale, therefore, was one-third to 3-times compared
489
490 165 to normal amount. These variables from the first part will be called “consumer related
491
492 166 variables” throughout the paper, and those from second part as “product related
493
494 167 variables”.

495
496
497 168 Consumers were classified based on their mouth behaviour (MB) using the JBMB™
498
499 169 typing tool, which sorts people in four groups (*Cruncher*, *Chewer*, *Sucker* and
500
501 170 *Smoosher*). The tool had consumers classify themselves, by picking the group of
502
503 171 pictures and that was “most like them”. The descriptions, for example, “I like foods that
504
505 172 I can crunch” were followed by foods with textures that were easy to “crunch”. It is
506
507 173 similar to three remaining groups of *Chewer*, *Sucker* and *Smoosher*. The classification
508
509 174 on mouth actions of consumers is based on the fact that individuals have a preferred
510
511 175 way to manipulate food in their mouths: some consumers (*Crunchers* and *Chewers*)
512
513 176 like to use their teeth to break down foods; while *Suckers* and *Smoosher*s, prefer to
514
515 177 manipulate food between the tongue and roof of the mouth. The difference within each
516
517 178 of the two groups lies in the hardness of preferred foods (Jeltema et al., 2015, 2016).
518
519 179 The classification of consumers in MB groups was used to investigate the effect of
520
521 180 different mouth behaviours on consumer expectations and prediction models in the
522
523 181 rest of this paper.

182 All the sensory evaluations were conducted in standardized individual booths
183 according to (ISO 8589:2007). Samples were served in plastic containers coded with
184 3-digit random numbers and in a sequential monadic manner following a balanced
185 presentation order. Thirty grams of each yoghurt was served to each assessor for all
186 the evaluations.

187 *2.3. Data analysis*

188 *2.3.1. Analysis of variance (ANOVA) on consumer expectations (liking, satiation,*
189 *satiety, portion)*

190 Because each consumer would be assigned to only one MB group, consumer and
191 MB group were not crossed. Rather, consumer was nested within MB group. The
192 design was unbalanced as MB groups had different numbers of consumers. The
193 unbalanced nested ANOVA was carried out on the ratings, considering sample (fixed
194 effect), MB group (fixed effect), consumer nested within MB group (random effect) and
195 interactions of sample and MB group (fixed effect) as sources of variation.

196 *2.3.2. PLS path modelling (PLS-PM)*

197 Considering the framework of consumer expectations where liking, satiation and
198 satiety influence each other and together they influence portion size, we will in this
199 paper focus on a path modelling (PM) approach. In particular we chose to use PLS
200 path modelling due to its many good properties (see for instance (Tenenhaus, Vinzi,
201 Chatelin, & Lauro, 2005))

202 Providing details of the PLS-PM algorithm is beyond the scope of this paper, but
203 they are available from (Tenenhaus et al., 2005; Vinzi, Chin, Henseler, & Wang, 2010).

649

204 As indicated in the introduction, main emphasis in the PLS-PM will be given to the
205 product variables, the main reasons being that the consumer variables generally had
206 a weak relation to product related measurements and that the relations were unstable
207 and therefore difficult to interpret when using a model reduction (see below). A brief
208 summary of the results will be given in the results section.

209 Because these blocks were rated on different scales, standardization between
210 blocks was applied by dividing each block according to the square root of the sum of
211 squares (Frobenius norm).

212 The procedure for handling data and obtaining model was illustrated in Fig. 1.

213 *Organization of data*

214 Since both consumer attitudes and demographics, as measured by a questionnaire,
215 as well as product related aspects such as liking and satiety were measured, a proper
216 organization of the data blocks was needed before submitting the data to analysis. This
217 challenge was discussed in depth by (Menichelli, Hersleth, Almøy, & Næs, 2014). In
218 that paper, it was proposed to let the consumers represent the rows and the different
219 questionnaire questions and liking of the different products represent the columns, i.e.
220 each product has a separate column of liking values. In cases with very many products
221 it was proposed to represent the liking values for all products by a few principal
222 components only. We will here use this strategy for all product related blocks, i.e. liking,
223 satiation, satiety and portion. Fig. 2 displays how the data set was organized for
224 analyses.

225 *Solving the one-dimensionality issue*

650
651
652 226 It is generally most appropriate to model sensory variables and also possibly
653
654 227 habits/attitudes variables as reflective blocks (Bollen & Lennox, 1991; Diamantopoulos
655
656 228 & Siguaw, 2006; Menichelli et al., 2014). As a reflective block, the manifest variables
657
658 229 (MVs) in the block are assumed to measure the same unique underlying concept
659
660 230 (Vinzi, Trinchera, & Amato, 2010). The full PLS-PM model requires in this case that all
661
662 231 blocks are uni-dimensional. Checking for uni-dimensionality with Cronbach's alpha
663
664 232 requires the MVs to be positively correlated (Tenenhaus et al., 2005). For these
665
666 233 reasons, some MVs should be replaced by its opposite form. In the *mental hunger*
667
668 234 block, for example, the item "Rate your current feeling of fullness" indicated the
669
670 235 negative correlation with its own block. The solution to fix this problem was to change
671
672 236 the sign of this item so that instead of "feeling of fullness" it reflected "feeling of hunger".
673
674 237 Similarly, for each block, the correlations of MVs and responding block were
675
676 238 considered, then the signs of MVs were changed if necessary before calculating
677
678 239 Cronbach's alpha.
679
680
681
682

683 240 Data comprised different blocks; consumer characteristics: *hunger and fullness*,
684
685 241 *attitudes toward healthfulness, attitudes toward taste*; and product characteristics:
686
687 242 *liking, expected satiation, expected satiety* and *portion-size selection*. These blocks
688
689 243 should be divided into separate blocks with the goal of controlling the uni-
690
691 244 dimensionality issues (as required by PLS-PM).
692
693

694 245 For the *hunger and fullness question*, each factor (i.e. mental Hunger, mental
695
696 246 Fullness, physical Hunger, physical Fullness) measured only one aspect of hunger and
697
698 247 fullness feelings (Karalus & Vickers, 2016). Similarly, each factor in *attitudes toward*
699
700 248 *healthfulness of foods, attitudes toward taste* measured one aspect of consumer
701
702 249 attitudes (Roininen et al., 1999).
703
704
705
706
707
708

709
710
711 250 PCA (Mardia, Kent, & Bibby, 1979) was applied to each product related block (i.e.
712
713 251 liking, satiation, satiety and portion) using double centered data, the scores and
714
715 252 loadings were computed. The rows now represent the consumers as described above.
716
717
718 253 For standard PCA of consumer data (i.e. in preference mapping studies), mean
719
720 254 centering for each consumer will usually be done, meaning that the additive differences
721
722 255 between consumers (i.e. different use of the scale) have been eliminated (T. Næs, P.
723
724 256 Brockhoff, & O. Tomic, 2010). Since each column is mean centered the standard way
725
726 257 in PLS-PM, this leads to double centered data (Menichelli et al., 2014), i.e. data is
727
728 258 mean centered across products and across consumers for each combination of sample
729
730 259 *i* and consumer *j*. By doing so, both the difference in level between the consumers and
731
732 260 the average differences between the products were eliminated. This means that the
733
734 261 PCA will focus on how the different consumer relate to the average consumer for each
735
736 262 product (Endrizzi, Gasperi, Rødbotten, & Næs, 2014; Endrizzi, Menichelli, Johansen,
737
738 263 Olsen, & Næs, 2011). This approach is supported by the fact that for the PCA done
740
741 264 without double centering, the first component represented only different use of the
742
743 265 scale with all consumers lying on one side of the first component.

744
745
746 266 The PCA revealed that all product blocks were multi-dimensional. An approach
747
748 267 based on interpreting the principal components scores and using them as separate
749
750 268 blocks was then applied (see also Menichelli et al., 2014). Two components described
751
752 269 most of the interesting information for each data block. By doing so, instead of the eight
753
754 270 values responding to the eight samples for each consumer rating (i.e. liking, satiation,
755
756 271 satiety, portion size), the scores from two PCA components were used as input (in
757
758 272 separate blocks) to the prediction model for each block.

759
760
761 273 In order to examine the meanings of PCA dimensions, sensory attributes from CATA
762
763 274 questionnaire were treated as supplementary observations. This was achieved by

768
769
770 275 projecting the frequencies of sensory attributes on the PCA space; that is, the factor
771
772 276 scores of the supplementary observations were not used to compute the principal
773
774 277 components (Abdi & Williams, 2010; T. Næs, P. B. Brockhoff, & O. Tomic, 2010).
775
776

777 278 The original blocks and separate blocks used in PLS path modelling are described
778
779 279 in Table 2.
780
781

782 280 *The path model used*

783
784

785 281 The path model given main attention in this paper is given in Fig. 3. The blocks were
786
787 282 introduced according to the theorized relation between them. The relationship between
788
789 283 liking and satiation, satiety as well as portion was established with respect to the
790
791 284 sequence of cognitive and physiological processes when people consume a food
792
793 285 product (Blundell et al., 2010). Based on that, liking was incorporated before satiation
794
795 286 (mostly influenced by sensory attributes) and satiety (imparted by sensory attributes,
796
797 287 cognitive, post-ingestive and post-absorptive). These expectations will be incorporated
798
799 288 into the framework to determine portion selection.
800
801
802

803 289 In the secondary path model comprising all blocks, all questionnaire variables were
804
805 290 used as input to the product related variables and the product related variables were
806
807 291 introduced according to the theorized relation between them as discussed above. The
808
809 292 consumer related variables (questionnaire) were assumed to influence consumer
810
811 293 expectations.
812
813
814

815 294 *Simplifying the model*

816
817

818 295 In order to simplify the path model, a reduction was tried by testing each of the links
819
820 296 by bootstrap based t-tests. Different sizes of p-values (0.1, 0.05 and 0.01) were tested
821
822 297 to validate the stability of the reduction.
823
824
825
826

827
828
829 298 The models should be compared on criteria such as the strength of the relations
830
831 299 between variables as well as direct and indirect effects. By definition, the direct effect
832
833 300 was that influence of one variable on another that was unmediated by any other
834
835 301 variables in a path model; the indirect effects of a variable were mediated by at least
836
837 302 one intervening variable (Bollen, 1989; Kaplan, 2009). For the models, main emphasis
838
839 303 was given to two components in this case, but the third component was also given
840
841 304 some attention.
842
843

844 305 All data were collected with EyeQuestion (Logic8 BV, The Netherlands) and
845
846 306 analyses were carried out using R software (R Core Team, 2018). The packages *pls*
847
848 307 (Sanchez, Trinchera, & Russolillo, 2017) and *semPLS* (Monecke & Leisch, 2012) were
849
850 308 used for performing PLS path modelling.
851
852

853 309 **3. Results**

854
855
856
857 310 First of all, the results from the unbalanced nested ANOVA (Table 3) revealed that
858
859 311 while *sample* was significant for liking, satiation, satiety and portion, the *MB group* was
860
861 312 not significant at test level of 0.05.
862
863

864 313 However, it is important to see that the interaction product:MB was statistically
865
866 314 significant for satiation, while it was not for the rest of consumer expectations,
867
868 315 suggesting that mouth behavior plays a role in the expectations of satiation. The
869
870 316 interaction indicates that consumers rated the expected satiation of a product
871
872 317 depending on the MB group they belonged (Fig. 4). It is reasonable as *chewers* and
873
874 318 *crunchers* on one side and *smooshers* on the other, fall into two major modes of mouth
875
876 319 actions which seem to have separated people by their primary mouth behavior,
877
878 320 preferring to use their teeth to break down foods vs manipulating it between the tongue
879
880 321 and roof of the mouth respectively (Jeltema et al., 2015, 2016). In particular, *chewers*
881
882
883
884
885

886
887
888 322 and *crunchers* differentiated between two groups of products: P2, P4, P6, P8 (thick
889
890 323 samples) in high satiation and P1, P3, P5, P7 (thin samples) expected as lower in
891
892 324 satiation. *Smooshers* however, tended to classify products into three groups in
893
894 325 descending order of satiation from P2, P4, P6, P8 (thick samples) and then
895
896 326 discriminating into two groups of these samples, depending on the particle size and
897
898 327 flavour level (P5, P7 and then P1, P3). This may suggest that the managing of the
899
900 328 samples between the tongue and the upper palate could make them more aware of
901
902 329 the flavour and particle size as drivers of satiation in thinner samples. The implication
903
904 330 of MB in the model will be further commented in the discussion section.

908 331 3.1. PCA for individual product blocks

910
911 332 Fig. 5 points out that the samples were separated on the first PC space for liking (a)
912
913 333 and expected satiety (b). On the first dimension, samples were split into two groups
914
915 334 regarding to liking, with P1, P5, P7 in one group and P2, P4, P6, P8 in the other. Then
916
917 335 the second dimension separated samples into two groups, P3, P4, P7, P8 on the top
918
919 336 and P1, P2, P5, P6 at the bottom of the dimension. It can be noted that the same
920
921 337 structure was relevant for liking, satiation and portion (data not shown for these last
922
923 338 two), but not for satiety. In that case, the importance of the first two dimensions was
924
925 339 interchanged. The first dimension separated samples into two groups of P4, P7, P8
926
927 340 and P1, P2, P3, P5, P6 (Fig. 5b). To understand this, one could look at these results
928
929 341 together with the sensory attributes as described by consumer in the CATA question.

932
933 342 For liking (Fig. 6a), the first dimension was explained by viscosity with *Thick* and
934
935 343 *Liquid* attributes located in the opposite sides, whereas the second dimension was
936
937 344 characterized by the particle-size (*Sandy* and *Pieces*). Similarly, these
938
939 345 characterizations were observed for satiation and portion size. As described above, for
940
941
942
943
944

945
946
947 346 satiety, the position of the two dimensions was switched, the first dimension became
948
949 347 the particle-size dimension and the second was the viscosity dimension (Fig. 6b).
950
951 348 These results are reasonable with regard to the design of experiment (viscosity,
952
953 349 particle-size and flavour intensity variables). More specifically, the samples P1, P3, P5,
954
955
956 350 P7 were designed as thin viscosity, the samples P2, P4, P6, P8 were thick in viscosity;
957
958 351 oat flour was added to the samples P3, P4, P7, P8 and oat flakes to the samples P1,
959
960 352 P2, P5, P6.
961
962

963 353 The third dimension was also taken into consideration. For liking and portion size, it
964
965 354 was described as the Sweet-Sour dimension, whereas for satiation and satiety, it was
966
967 355 the Sandy-Pieces dimension. The separation of sensory attributes was however not
968
969 356 relevant enough to have a clear interpretation or naming of the third dimension. From
970
971 357 these results, instead of eight ratings in response to eight samples, the three
972
973 358 dimensions, the so-called *viscosity* (V), *particle-size* (P) and the *third dimension*, will
974
975
976 359 be used for the analyses throughout the paper.
977
978

979 360 3.2. *The prediction model*

982 361 *The model of product related variables only (prod model, 2 first PCA components)*

985 362 To simplify the graphical interpretation task, and due to the excessive number of
986
987 363 variables in the data set, the focus will be on the block of product related variables. At
988
989 364 first, the full prod model was considered, and then the stability of model was
990
991 365 investigated by comparing some reduced models responding to different p-values (0.1,
992
993 366 0.05 and 0.01). Afterwards, the specific model should be chosen to explain the main
994
995 367 relations between variables.
996
997
998
999
1000
1001
1002
1003

1004
1005
1006 368 The relations between product variables in the full model were displayed in Fig. 7;
1007
1008 369 some relations were well defined, however, other relations with the path coefficients,
1009
1010 370 i.e. direct effects, were equal to zero and almost zero (*LikingV-SatietyP*, *LikingV-*
1011
1012 *PortionP*, *SatiationP-PortionP* and *SatietyV-PortionV*). These relations should be
1013 371
1014
1015 372 eliminated from the model for obtaining the more stable models.
1016
1017

1018 373 The validation of the model simplification pointed out that the main relations between
1019
1020 374 product related variables were stable with different p-values (0.1, 0.05, 0.01). In other
1021
1022 375 words, the reduced models had some slight changes, but the main trend was not
1023
1024 376 changed. The significant relations decreased in the reduced models with respect to p-
1025
1026 377 values. Comparing to the reduced models of p-value 0.1, in the reduced model of p-
1027
1028 378 value 0.05, the relations *LikingV-SatiationP*, *LikingP-SatietyP*, *SatiationP-PortionV*
1029
1030 379 were eliminated. In the light of this trend, in the reduced model of p-value 0.01, the
1031
1032 380 relations *SatiationV-PortionP*, *LikingP-SatiationV*, *SatiationP-SatietyV* continued to be
1033
1034 381 removed. Apart from *LikingP-SatietyP*, all eliminated relations did not display the
1035
1036 382 relations of consumer expectations on the specific dimension (*viscosity* or *particle-*
1037
1038 383 *size*). That is possible explanation why these relations were not stable with different p-
1039
1040 384 values.
1041
1042
1043

1044 385 In addition to the path coefficients, the explained variances of endogenous blocks
1045
1046 386 were considered (Table 4). It was not surprising that these blocks were explained
1047
1048 387 similarly for models with different p-values. Among those, *PortionP* was the most
1049
1050 388 explained block (R2: 0.48 - 0.50), whereas *SatiationP* was the least explained one (R2:
1051
1052 389 0.09 – 0.11). These results supported the above findings in which the product models
1053
1054 390 were stable with different p-values.
1055
1056
1057
1058
1059
1060
1061
1062

1063
1064
1065 391 Without loss of generality, the reduced model of p-value 0.1 was selected to account
1066
1067 392 for the relations between product variables. The path diagram was depicted in Fig. 8
1068
1069 393 and the direct/indirect effects were summarized in Table 5. In the model, liking had
1070
1071 394 positive and strong effects on portion with the path coefficients of 0.46 and 0.71 for
1072
1073 395 *viscosity* and *particle-size* dimensions, respectively. Accordingly, liking was a good
1074
1075 396 predictor for satiation and satiety. It is noteworthy that while liking directly influenced
1076
1077 397 satiation (*LikingV-SatiationV*: 0.30, *LikingP-SatiationP*: 0.37), it did not contribute
1078
1079 398 directly to satiety for each dimension. The effect liking-satiety was indirect through
1080
1081 399 satiation, that is, liking influenced satiation, which in turn, imparted satiety (*LikingV-*
1082
1083 400 *SatiationV-SatietyV*: 0.13, *LikingP-SatiationP-SatietyP*: 0.15). On this relation, it is
1084
1085 401 interesting to find that *LikingV* had indirect and positive effect on *SatietyV*, and on the
1086
1087 402 opposite side, *LikingP* had direct and negative effect on *SatietyV* (-0.29). To sum up,
1088
1089 403 the strongest indirect relation was the relation between liking and satiety; the direct
1090
1091 404 effects confirmed the strong relations of liking-portion, liking-satiation, satiation-satiety
1092
1093 405 and especially *LikingP-SatietyV*.

1098 406 *The model with three components*

1101 407 In this part, models were built taking into account three dimensions of viscosity,
1102
1103 408 particle-size and the third dimension. Then, the comparisons between the models with
1104
1105 409 different p-values. The results showed that the reduced model with p-value 0.05
1106
1107 410 seemed to be the optimal model because it kept enough information for interpretation
1108
1109 411 with less complexity. For *viscosity* and *particle-size* dimension, the relations were still
1110
1111 412 liking-portion and liking-satiation-satiety, for the third dimension, however, there were
1112
1113 413 some interactions. The third dimension seemed to be the mixture of viscosity and
1114
1115 414 particle-size dimensions; that is, it played the role of viscosity dimension in some
1116
1117 415 relations, and particle-size in other relations. Thus, including the third dimension in the
1118
1119
1120
1121

1122
1123
1124 416 model was not relevant for interpretation and more difficult to understand. These
1125
1126 417 results supported for the decision for which only two dimensions (i.e. *viscosity* and
1127
1128 418 *particle-size*) should be used in the model.
1129
1130

1131
1132 419 *The model of consumer and product variables (con-prod model)*
1133

1134 420 The relations in the *con-prod* model often followed the specific dimensions, i.e.
1135
1136 421 particle-size (P) and viscosity (V) dimension. In other words, the direct relations of
1137
1138 422 liking-portion and indirect relation of liking-satiation-satiety were relevant for each
1139
1140 423 dimension. The stability of this model was also investigated with different p-values. The
1141
1142 424 results (data not shown here) revealed that the relations between product variables
1143
1144 425 were stable and similar to the common pattern of the *prod* model described previously,
1145
1146 426 whereas those of consumer variables were quite sensitive with different p-values. In
1147
1148 427 order to eliminate some non-significant relationships and keep enough information for
1149
1150 428 interpretation, the p-value of 0.05 was chosen for the reduced model. In general lines,
1151
1152 429 hunger and fullness feelings as measured by the questionnaires influenced both liking
1153
1154 430 and satiation/satiety as measured for the products. *Physical hunger* had a negative
1155
1156 431 effect on *liking*; *mental fullness* negatively imparted *satiation* and positively imparted
1157
1158 432 *satiety*. For variables related to consumer attitudes towards healthfulness and taste of
1159
1160 433 food, they only influenced liking.
1161
1162
1163
1164

1165 434 *3.3. The influence of individual differences on the predicted model*
1166
1167

1168 435 The results of this part of the study looked into the effects of the variable *eating-style*
1169
1170 436 on the prediction model. Based on consumers' mouth behaviors as classified with the
1171
1172 437 JBMB™ typing tool, consumers can be classified into four major groups, however, in
1173
1174 438 the present work consumers fell into three groups only: *Chewer*, *Cruncher* and
1175
1176 439 *Smoosher*, no *Sucker* was identified by the data. The path diagrams of these three
1177
1178
1179
1180

1181
1182
1183 440 groups are depicted in Fig. 9. Basically, a similar model was obtained in general lines
1184
1185 441 to predict portion for the three groups of consumers. Nevertheless, there was
1186
1187 442 noteworthy difference in *LikingV-PortionV*. While the relation was positive and strong
1188
1189 443 for *Chewers* (0.44) and *Crunchers* (0.65), it seemed to be weak, and if any, negative
1190
1191 444 (-0.11) for *Smooshers*. Particularly, *Smooshers* might use only *particle-size* for
1192
1193 445 predicting portion; as a strong relation *LikingP-PortionP* (0.68) was observed in Fig.
1194
1195 446 9c. The results are in agreement with previous studies (Jeltema et al., 2015, 2016),
1196
1197 447 stating that consumers used different strategies to manipulate foods and this
1198
1199 448 influenced their expectations. In this study, *Chewers* and *Crunchers* seemed to use
1200
1201 449 both two sensory dimensions (*viscosity* and *particle-size*) for estimating the *Portion*,
1202
1203 450 meanwhile *Smooshers* used *particle-size* only.
1204
1205

1207

1208 451 4. Discussion

1209 1210 452 4.1. The relation between liking and satiety

1211
1212
1213 453 The prod model (Fig. 7) displays the general framework which describes the
1214
1215 454 relationships between consumer expectations. This model pointed out that an increase
1216
1217 455 in liking leads to an increase in prospective portion size (both when driven by particle
1218
1219 456 size or by viscosity). In addition, a higher liking could produce greater satiety as a
1220
1221 457 consequence of a greater satiation. It is compatible with the results of the previous
1222
1223 458 studies (De Graaf, De Jong, & Lambers, 1999; Johnson & Vickers, 1992; Yeomans,
1224
1225 459 1996). These authors studied the effect of liking on satiation, highlighting that the
1226
1227 460 absence of the effect of liking on subsequent satiety was clear. Note that the results
1228
1229 461 from the previous studies have been achieved in terms of direct relations only. In the
1230
1231 462 present study, both direct and indirect effects are interpreted. When the interactions
1232
1233 463 are included in the model, the interpretation becomes more complicated. Different

464 dimensions of liking resulted in different effects on satiety; *LikingP-SatietyV* with
465 negative effect and *LikingV-SatietyV* with positive effect. Note that the latter is indirect
466 effect through *SatiationV*, which is obtained by multiplying the path coefficient of
467 *LikingV* on *SatiationV* with the path coefficient of *SatiationV* on *SatietyV*.

468 From the sensory perspective, sensory perception is not a single event but a
469 dynamic process with a series of events (Labbe, Schlich, Pineau, Gilbert, & Martin,
470 2009). The relation between these sensations and sensory-specific satiation/satiety
471 are not static during consumption (Karen, 2004; Morell, Fiszman, Varela, & Hernando,
472 2014). In a previous study done on the same yoghurt samples of the present study,
473 the product trajectories, highlighted by dynamic profiling via TCATA, pointed out the
474 common pattern in temporal profiles in which the samples were first separated by
475 *viscosity* and then by *particle-size* (Nguyen et al., 2018). This would support the
476 hypothesis of a sequential assessment of liking linked to the sequential perception from
477 viscosity (*LikingV*) to particle-size (*LikingP*). In other words, *this would highlight the*
478 *temporal dimension of liking assessment, linked to the different* stages of the dynamic
479 sensory perception of texture.

480 In the results, *viscosity* and *particle-size* have been interpreted as two orthogonal
481 dimensions on the PCA space (Fig. 6); however, from a perceptual point of view, these
482 properties can interact during the oral processing. Considering the rheology of a
483 suspension (as the yogurt model here), if the total mass of particles in a suspension is
484 kept constant but the particle size of the is reduced, then viscosity in the system would
485 increase (Hardacre, Lentle, Yap, & Monro, 2018; Mueller, Llewellyn, & Mader, 2010;
486 Tarancón, Hernández, Salvador, & Sanz, 2015). In the present study, a decrease in
487 particle size of the oat flakes would contribute to an increase in viscosity in the yoghurt
488 samples. For that reason, *LikingP* might play a role of “-*LikingV*”. In the prediction

1299
1300
1301 489 model, the relation of *LikingV-SatietyV* has a positive effect, meaning that, if consumers
1302
1303 490 like a sample with thick viscosity, they will perceive it as more satiating as well.
1304
1305 491 Consequently, *LikingP* has negative influence on *SatietyV*, as a yogurt with bigger
1306
1307
1308 492 particles could be less viscous, and consequently perceived as less satiating.
1309

1310
1311 493 In present years, many studies have investigated the role of viscosity and food
1312
1313 494 particles on expectations of satiation and satiety. These studies stated that both
1314
1315 495 viscosity and solid food particles have been reported as modulators of expectations
1316
1317 496 about satiety in which an increase in the perceived thickness was positively correlated
1318
1319 497 with the expected satiation, and more solid foods may evoke increased satiety
1320
1321 498 (Hogenkamp & Schiöth, 2013; Hogenkamp et al., 2011; Marcano, Morales, Vélez-Ruiz,
1322
1323 499 & Fiszman, 2015). The explanations based on the oro-sensory exposure; in particular,
1324
1325 500 higher viscosity in a food leads to longer oro-sensory stimulation (Mars, Hogenkamp,
1326
1327 501 Gosses, Stafleu, & De Graaf, 2009) and more solid products require more labor and
1328
1329 502 time in the mouth, causing longer oro-sensory exposure (Hogenkamp & Schiöth,
1330
1331 503 2013). As a consequence, an increase in oral processing may result in higher satiety
1332
1333 504 (Forde, van Kuijk, Thaler, de Graaf, & Martin, 2013; Hogenkamp & Schiöth, 2013). On
1334
1335 505 the contrary, Tarrega and colleagues have shown that a more viscous product base
1336
1337 506 increased the mean expected satiation regardless of the food particle added (Tarrega,
1338
1339 507 Marcano, & Fiszman, 2016). Unlike to those studies, the present study indicated that
1340
1341 508 while viscosity positively imparted satiety, food particle negatively influenced satiety;
1342
1343 509 that is, bigger particles lead to less satiating perception.
1344
1345
1346

1347
1348 510 This result is not observed for *SatietyP*. The possible reason is that the “particle size
1349
1350 511 – viscosity” relation is only one direction from particle-size to viscosity, not in the
1351
1352 512 opposite direction. Apart from the viscosity effect of the reduced particle size, other
1353
1354 513 sensory perceptions related to the oral process might be affecting satiety perception in
1355

514 different directions. For example, the effect of the small particles might have in the
515 eating rate; having very small particles in the mouth can require longer work with the
516 tongue to being able to swallow the product. This sandy perception can in turn affect
517 liking in different ways, depending on the preferences and mouth behaviour.

518 *4.2. The relation between consumer characteristics and consumer expectations*

519 Focusing on expected satiety, higher mental fullness (*mFull*) scores predicted larger
520 decreases in viscosity related satiation (*SatiationV*). The finding is in accordance with
521 Mattes and colleagues, pointing out that a higher expected satiety led to decrease in
522 hunger and increase in fullness immediately after consuming the food (Mattes &
523 Vickers, 2018). As opposed to satiety, mental fullness (*mFull*) had negative effect on
524 satiation (*mFull* scores predicted larger increases in viscosity related satiety -
525 *SatietyV*), meaning that the feeling of mental fullness might reduce consumers'
526 satiation.

527 While mental fullness significantly influenced satiation and satiety expectation,
528 physical hunger (*pHunger*) influenced liking; in particular, liking related to viscosity
529 (*LikingV*). When consumers rated a higher physical hunger, they tended to dislike
530 yogurts that were thicker. However, *pHunger* was not the only predictor, *craving* and
531 *reward* also contributed to the changes of *LikingV*. The strengths of these relations
532 (*craving-LikingV*, *reward-LikingV*) are similar and positive. That suggests that liking
533 should be considered as complex concept which is imparted by several factors, at least
534 in the present study, such as hunger and fullness feelings and attitudes to healthiness,
535 and taste of foods.

536 *4.3. Determining number of components*

1417
1418
1419 537 In order to maintain the uni-dimensionality of data blocks in the PLS-PM approach,
1420
1421 538 PCA was applied on each data block and then only the first two components are
1422
1423 539 selected for subsequent analyses. In the present study, the selection was not very
1424
1425 540 difficult due to the fact that the samples have been formulated from a design of
1426
1427
1428 541 experiment of viscosity, particle-size and flavour intensity variables. However, when
1429
1430 542 more complex samples with a wide range of sensory perceptions were used, the
1431
1432 543 selection of the number of dimensions in the model could be indeed a difficult task in
1433
1434 544 itself. This problem could be solved with some other approaches such as SO-PLS path
1435
1436 545 modelling (Næs, Tomic, Mevik, & Martens, 2011) or Path-ComDim (Cariou, Qannari,
1437
1438 546 Rutledge, & Vigneau, 2018). These approaches can be used for any dimensionality of
1439
1440 547 the blocks of variables. Research work is needed to further compare these approaches
1441
1442
1443 548 to deeper understand advantages and limitations.

1444 1445 1446 549 **5. Conclusions**

1447
1448
1449 550 This paper has shed some light on the question of whether “quality can replace
1450
1451 551 quantity” although the answer is not straightforward. With the model obtained by PLS-
1452
1453 552 PM, liking played an important role in predicting portion selection. More specifically, a
1454
1455 553 higher liking meant a bigger portion selection for the semisolid system under study.
1456
1457 554 Besides that, satiation and satiety could be predicted from liking directly and indirectly,
1458
1459 555 the understanding of the implications, however, needs to be considered carefully due
1460
1461 556 to the dynamic and multiparametric nature of these expectations.

1462
1463
1464 557 The present study suggests that PLS-PM could be an appropriate tool to explain the
1465
1466 558 relationships between consumer attitudes, product assessment and expectations. In
1467
1468 559 this case study, consumer expectations of liking, satiation, satiety, and prospective
1469
1470
1471 560 portion were clearly two dimensional and it has been shown how it can be interpreted.

765 Figure Captions

766 Fig. 1. Schematic diagram of data handling and model selection.

767 Fig. 2. Different types of data sets and their relations.

768 *The first data set consists of consumer characteristics for each consumer, related to*
769 *hunger and fullness feelings, attitudes toward healthfulness, taste of foods;*

770 *The second data set comprises eight ratings (responding to eight products) for each*
771 *expectation (liking, satiation, satiety, portion) for each consumer. Specifically, there are*
772 *four data blocks and each of the block includes eight columns with the ratings of the*
773 *eight products.*

774 Fig. 3. Path model of product related variables (*prod* model).

775 *V and P were the notation of viscosity and particle-size dimension, respectively.*

776 Fig. 4. Interaction plot (product:MB) for expected satiation.

777 Fig. 5. PCA on double-centered data for Liking (a); Expected satiety (b).

778 Fig. 6. CATA attributes profiled in the PCA space for Liking (a); Expected satiety (b).

779 Fig. 7. Path diagram for the full *prod* model.

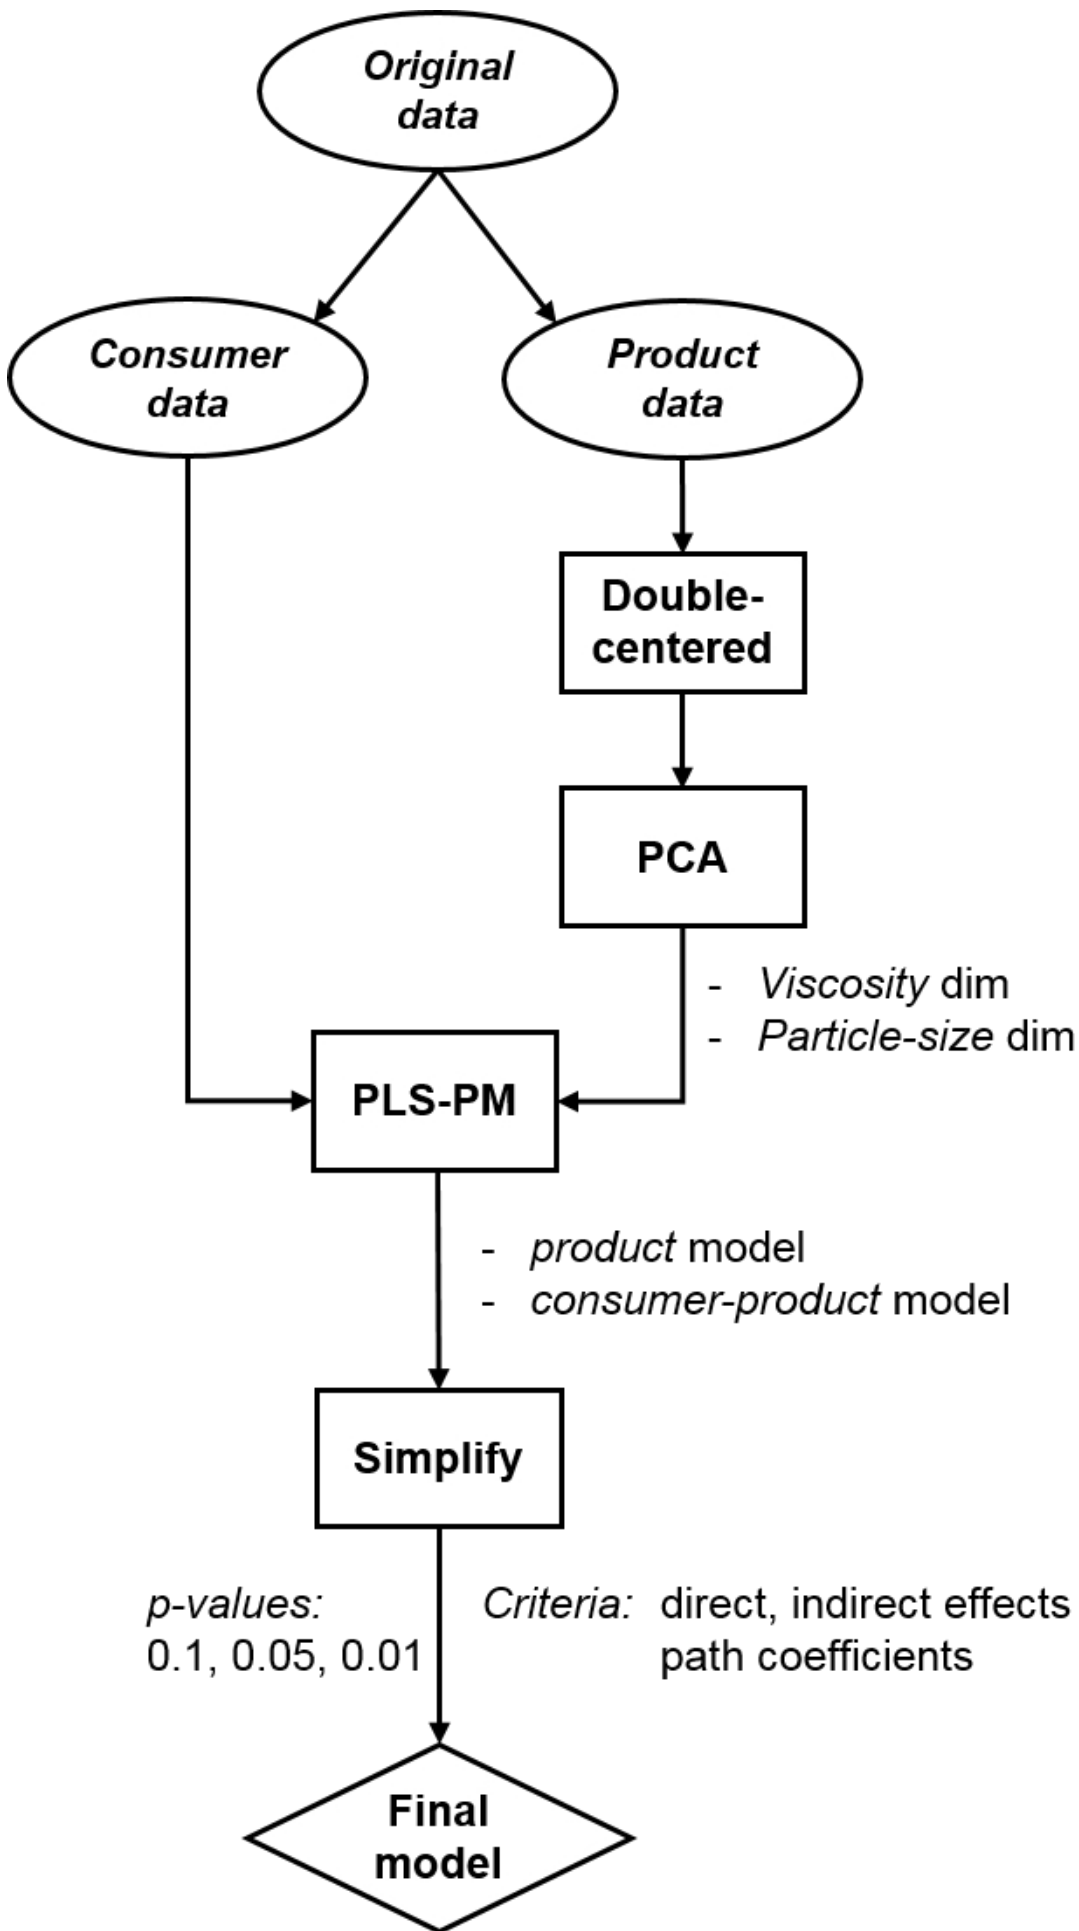

780 *The 'blue' lines stood for the positive relations, the 'red' lines dedicated for negative*
781 *relations, the thickness of the lines indicated the strengths of the relations and the*
782 *numeric values together lines as the path coefficients (direct effects) between*
783 *variables.*

784 *V and P were the notation of viscosity and particle-size dimension, respectively.*

785 Fig. 8. Path diagram for the reduced *prod* model with p-values of 0.1.

786 Fig. 9. The path diagram for consumer-product model with p-value of 0.05 for Chewers
787 (a), *Crunchers* (b) and *Smooshers* (c).
